### Scope

This WPD applies to the process of managing raised intracranial pressure

### Materials

WPD 12: Lumbar Puncture

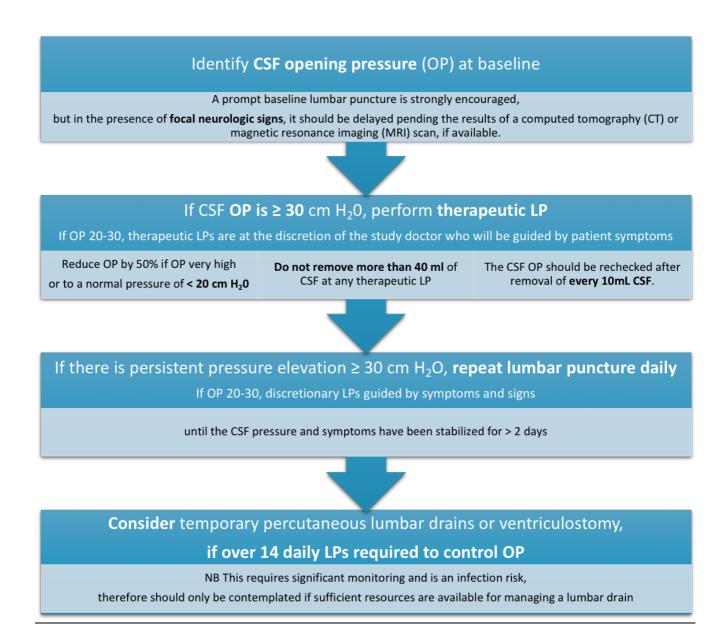

- Half of HIV-infected patients with CM have a CSF opening pressure of >25 cmH<sup>2</sup>O, with roughly a quarter of patients having a very high pressure of >35 cmH<sup>2</sup>O. High pressure is associated with worse symptoms, including headache, nausea, diplopia secondary to sixth nerve palsies, and altered mental status.
- Repeated daily therapeutic lumbar punctures are sufficient to control raised pressure in the majority of patients.
- All patients who have focal neurological signs (except VI<sup>th</sup> cranial nerve palsy which is often a false localising sign) should, if possible, have a contrast enhanced brain CT to identify mass lesions that may increase the risk of lumbar puncture. If no CT scan is available, the balance of risk favours performing a lumbar puncture.
- Cryptococcal meningitis patients should have an admission lumbar puncture CSF opening pressure recorded. Patients admitted to the study, regardless of their initial opening pressure, will undergo serial lumbar punctures on days 1, 7 and 14 of their admission.
- The opening pressure must be measured and documented for each and every lumbar puncture.
- Where study patients have raised intracranial pressure secondary to cryptococcal meningitis, the patient's CSF will be drained as often as required until the opening pressure normalises.
- Raised intracranial pressure is defined as a CSF opening pressure > 20 cm H<sup>2</sup>0.
- A therapeutic lumbar puncture aims to provide lumbar drainage sufficient to achieve a closing pressure  $\leq 20 \text{ cm H}^20 \text{ or } 50\%$  of the initial opening pressure.
- If OP >30 cm H<sub>2</sub>O, daily therapeutic LPs should be undertaken. If OP 20-30 cm H<sub>2</sub>O, therapeutic LPs are at the discretion of the study doctor who will be guided by patient symptoms.
- Usually no more than 40mls CSF will be drained at any one therapeutic lumbar puncture.
- The CSF pressure should be rechecked after removal of every 10ml CSF.
- Where repeated lumbar punctures over >14 days fail to control raised intracranial pressure, and the
  patient is deteriorating, lumbar drains may be considered. However, the high local rates of nosocomial
  infection and the lack of nursing staff trained to care for such drains are important factors to take into
  consideration.

## Please note:

- Mannitol has no proven benefit and is <u>not recommended</u>.
- Acetazolamide <u>should be avoided</u> to control increased intracranial pressure.
- Corticosteroids <u>should not routinely be used</u> during induction therapy for HIV-associated cryptococcal meningitis.

## Figure 1. Management of raised ICP diagram

## Training

Each staff member receives or has direct access to applicable Working Practice Documents (WPDs).

Each staff member reviews the applicable WPDs once a year.

All WPD training is documented and tracked in the training log located in the Investigator Site File (ISF)

New staff are trained on applicable WPDs within 30 days of employment and all WPDs within 90 days of employment.

Staff members whose duties fall within this WPD scope are retrained within 14 days of the approval of each WPD revision.
